

# Introduction to Functional Programming with Haskell - RCOS Presentation

Avi Weinstock

February 27, 2015

# What characterizes Functional Programming?

- ▶ Abstraction of common patterns via higher order functions
- ▶ A mathematical use of the term "function" (as a pure mapping from input to output), as opposed to the concept of procedures (e.g. in C)

# What is Haskell?

A general-purpose programming language that:

- ▶ Encourages a functional style of programming
- ▶ Enables very short, readable code
- ▶ Has static typechecking, with type inference
- ▶ Compiles to native code, in the same efficiency class as Java/C# (can be made as performant as Assembly/C/C++, with some effort)

# Hello world

► `main = putStrLn "Hello, world!"`

► `main = do  
 putStrLn "Enter a string: "  
 str <- getLine  
 putStrLn ("Echo: " ++ str)`

# Examples with numbers

- ▶ 

```
factorial n = product [1..n]
```
- ▶ 

```
dotProduct xs ys = sum $ zipWith (*) xs ys
dotProduct' xs ys = sum (zipWith (*) xs ys) -- equivalent definition
magnitude xs = sqrt $ dotProduct xs xs
```
- ▶ 

```
divides n i = (n `mod` i) == 0
isPrime n = not $ any (divides n) [1..n]
isPrime' n = not (any (divides n) [1..n]) -- equivalent definition
```

## Examples with numbers (continued)

- ▶ 

```
fibonaccis = 1 : 1 : zipWith (+) fibonaccis (tail fibonaccis)
```
- ▶ 

```
approxDerivative epsilon f x = (f (x+epsilon) - f x) / epsilon
```
- ▶ 

```
stars n = replicate (floor n) '*'  
showLines = putStr . unlines  
prepend = zipWith ((++) . show)  
plot f xs = showLines $ prepend xs (map (stars . f) xs)
```

# Execution of examples

```
ghci> :load haskell_lecture_numberslide.hs
[1 of 1] Compiling Main                ( haskell_lecture_numberslide.hs, interpreted )
Ok, modules loaded: Main.

# Functions used in previous examples

```
($) :: (a -> b) -> a -> b
```

```
f $ x = f x
```

```
(.) :: (b -> c) -> (a -> b) -> (a -> c)
```

```
(f . g) x = f (g x)
```

```
not :: Bool -> Bool
```

```
any, all :: (a -> Bool) -> [a] -> Bool
```

```
zip :: [a] -> [b] -> [(a, b)]
```

```
zipWith :: (a -> b -> c) -> [a] -> [b] -> [c]
```

```
sum, product :: Num a => [a] -> a
```

```
replicate :: Int -> a -> [a]
```

```
putStr, putStrLn :: String -> IO ()
```

# Map and Reduce

```
map :: (a -> b) -> [a] -> [b]
map f [] = []
map f (x:xs) = (f x):(map f xs)

map' f = foldr ((:) . f) [] -- equivalent definition

foldr :: (a -> b -> b) -> b -> [a] -> b
foldr f acc [] = acc
foldr f acc (x:xs) = f x (foldr f acc xs)
```

map applies its function to every element of a list.

foldr uses the provided function to reduce/aggregate the list into some value, starting from a seed.

Folds are very general, and can be used to implement many types of loops.

Definition of foldl in Python:

```
def foldl(f, init, xs):
    acc = init
    for x in xs:
        acc = f(acc, init)
    return acc
```

# Reduce (continued)

More definitions of things in terms of `foldr`:

```
map f = foldr ((:) . f) []  
  
sum = foldr (+) 0  
  
product = foldr (*) 1  
  
concat = foldr (++) []  
  
all p = foldr ((&&) . p) True  
  
any p = foldr ((||) . p) False
```

# Typeclasses

With this definition:

```
instance Num a => Num [a] where
    (+) = zipWith (+)
    (*) = zipWith (*)
    (-) = zipWith (-)
    negate = map negate
    abs = map abs
    signum = map signum
    fromInteger = cycle . return . fromInteger
```

Expressions like these become valid:

```
1 + [1,2,3]
2 * [2..10]
-[6,2,8]
abs [-5..5]
```

# Currying, Sections, and Infix

The following are all equivalent (via currying):

```
f g x y = zipWith g x y
f g x = zipWith g x
f g = zipWith g
f = zipWith
f g x = \y -> zipWith g x y
f g = \x y -> zipWith g x y
f = \g x y -> zipWith g x y
```

These are equivalent triples (via sections, and infix):

```
g x = x + 1
g = (+1)
g x = (+) x 1
```

```
h x = x 'mod' 2
h = ('mod' 2)
h x = mod x 2
```

```
i x = 2 'mod' x
i = (2 'mod')
i x = mod 2 x
```

Note that  $h \neq i$ , since `mod` is not commutative.

# TIMTOWTDI - There's More Than One Way To Do It

## Functions introduced:

```
ord :: Char -> Int
chr :: Int -> Char

interact :: (String -> String) -> IO ()

forever :: Monad m => m a -> m b
```

```
import Control.Monad
import Data.Char

caesarCipher shift = map (chr . ('mod' 256) . (+ shift) . ord)

main1 = forever $ do
    plaintext <- getLine
    let ciphertext = caesarCipher 3 plaintext
    putStrLn (caesarCipher 3 plaintext)

main2 = forever (getLine >>= (putStrLn . caesarCipher 3))

main3 = interact (caesarCipher 3)
```

# Quicksort

```
{-# LANGUAGE NoMonomorphismRestriction #-}
import Control.Monad
import Control.Monad.ST
import Data.STRef
import qualified Data.Vector as V
import qualified Data.Vector.Mutable as VM

import Data.List
import Test.QuickCheck

partitionByST cmp vec lo hi = VM.read vec pivotIdx >>= aux lo lo hi where
  pivotIdx = lo + ((hi-lo) `div` 2)
  aux i j n mid | j <= n = do
    a_j <- VM.read vec j
    case cmp a_j mid of
      LT -> VM.swap vec i j >> aux (i+1) (j+1) n mid
      GT -> VM.swap vec j n >> aux i j (n-1) mid
      EQ -> aux i (j+1) n mid
  aux i j n mid = return (i, j)
```

# Quicksort (continued)

```
quicksortByST cmp vec = aux 0 (VM.length vec - 1) where
  aux lo hi = when (lo < hi) $ do
    (leftMid, rightMid) <- partitionByST cmp vec lo hi
    aux lo leftMid
    aux rightMid hi

quicksortBy cmp vec = V.modify (quicksortByST cmp) vec

quicksort = quicksortBy compare

runTests = quickCheck matchesListSort where
  matchesListSort :: [Int] -> Bool
  matchesListSort x = (sort x) == (V.toList . quicksort $ V.fromList x)
```
